# Sequence Learning

- British Left Waffles on Falkland Islands
  - -(N, N, V, P, N, N)
  - -(N, V, N, P, N, N)
- Segmentation 中国十四个边境开放城市经济建设成就显著
  - -(s, b, i, b, i)

中国 十四 个 边境 开放 城市 经济 建设 成就 显著

China 's 14 open border cities marked economic achievements

# Sequence Learning

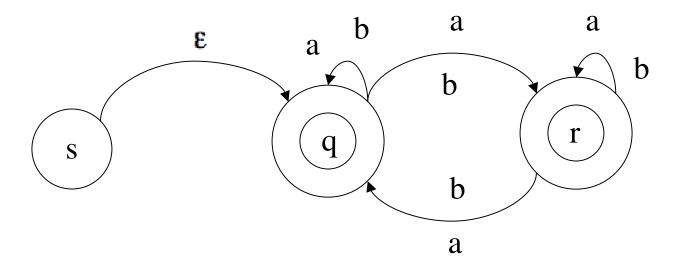

3 states: N, V, P

**Observation sequence**:  $(o_1, \dots o_6)$ 

**State sequence** (6+1): (*Start*, *N*, *N*, *V*, *P*, *N*, *N*)

#### Finite State Machines

Mealy Machine

#### Finite State Machines

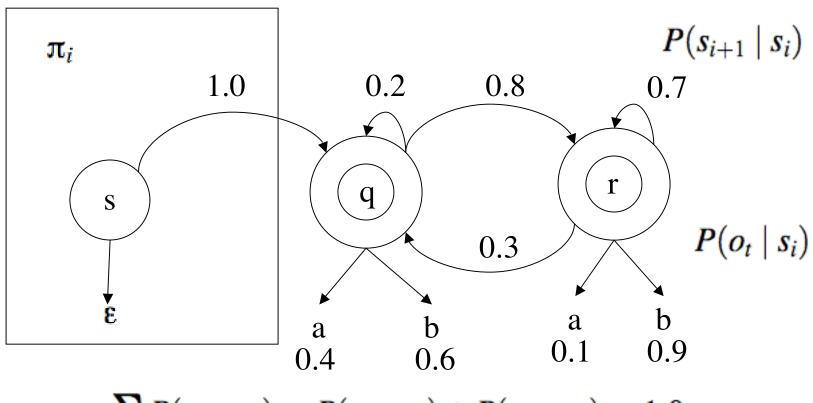

# s q r a b a b emission

Moore Machine

#### Probabilistic FSMs

- Each transition is associated with a transition probability
- Each emission is associated with an *emission probability*
- Two conditions:
  - All outgoing transition arcs from a state must sum to 1
  - All emission arcs from a state must sum to 1

#### Probabilistic FSMs

$$\sum_{x} P(q \rightarrow x) = P(q \rightarrow r) + P(q \rightarrow q) = 1.0$$

$$\sum_{x} P(\mathsf{emit}(q, x)) = P(\mathsf{emit}(q, a)) + P(\mathsf{emit}(q, b)) = 1.0$$

#### Hidden Markov Models

- There are n states  $s_1, ..., s_i, ..., s_n$
- The emissions are observed (input data)
- Observation sequence  $\mathbf{O} = (o_1, ..., o_t, ..., o_T)$
- The states are not directly observed (hidden)
- Data does not directly tell us which state  $X_t$  is linked with observation  $o_t$

$$X_t \in \{s_1,\ldots,s_n\}$$

#### Markov Chains vs. HMMs

• Given an observation sequence

$$\mathbf{O} = (o_1, ..., o_t, ..., o_T)$$

- An *n*th order Markov Chain computes the probability  $P(o_1, ..., o_t, ..., o_T)$
- An HMM computes the probability  $P(X_1, ..., X_{T+1}, o_1, ..., o_T)$  where the state sequence is *hidden*

# Properties of HMMs

Markov assumption

$$P(X_t = s_i \mid \ldots, X_{t-1} = s_j)$$

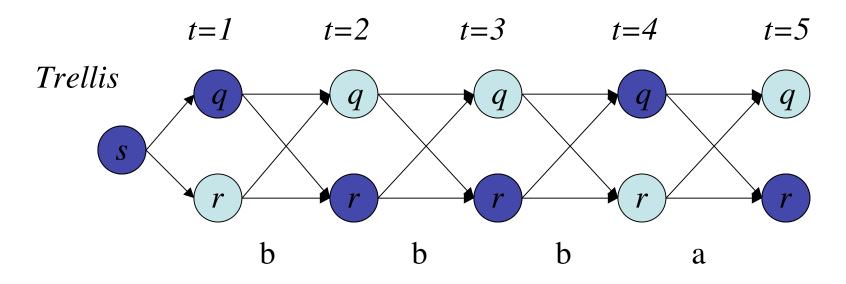

• Stationary distribution

$$P(X_t = s_i \mid X_{t-1} = s_j) = P(X_{t+l} = s_i \mid X_{t+l-1} = s_j)$$

# HMM Algorithms

- HMM as language model: compute probability of given observation sequence
- HMM as parser: compute the best sequence of states for a given observation sequence
- HMM as learner: given a set of observation sequences, learn its distribution, i.e. learn the transition and emission probabilities

# Best Path (Viterbi) Algorithm

- Key Idea 1: storing just the best path doesn't work
- Key Idea 2: store the best path upto *each* state

# Forward-Backward Algorithm

$$\alpha_{k}(t-1) \xrightarrow{k} \xrightarrow{m} \beta_{m}(t+2)$$

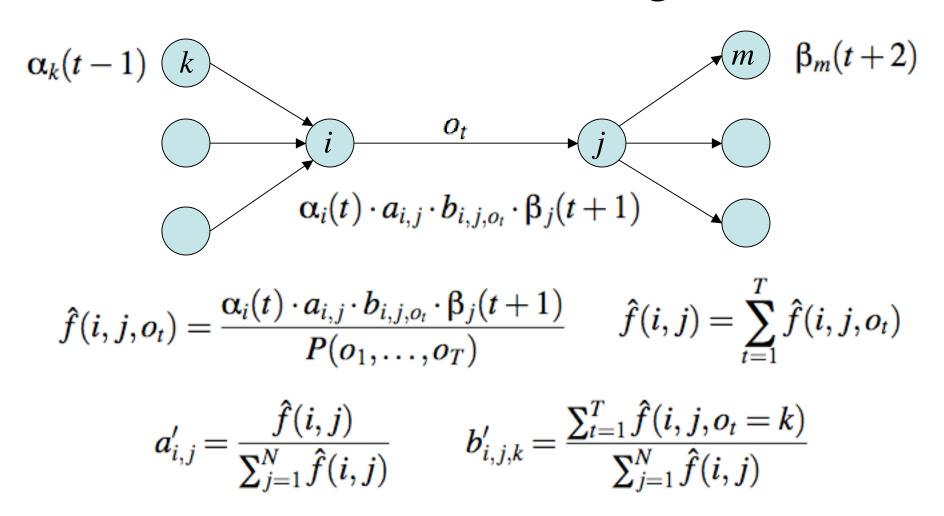

$$\alpha_{i}(t) \cdot a_{i,j} \cdot b_{i,j,o_{t}} \cdot \beta_{j}(t+1)$$

$$\alpha_{i}(t) = \sum_{k=1}^{N} a_{k,i} \cdot b_{k,i,o_{t-1}} \cdot \alpha_{k}(t-1)$$

$$\beta_{j}(t+1) = \sum_{m=1}^{N} a_{j,m} \cdot b_{j,m,o_{t+1}} \cdot \beta_{m}(t+2)$$

$$P(o_{1}, \dots, o_{T}) = \sum_{i=1}^{N} \alpha_{i}(T+1) = \sum_{i=1}^{N} \pi_{i} \cdot \beta_{i}(1)$$

# Forward-Backward Algorithm

# Forward-Backward Algorithm

- Each iteration provides new values for all the parameters
- But are the new parameters any better? How can we tell?
- Compute cross entropy
- For HMMs, Baum 1977 shows that cross entropy will always be non-increasing (later generalized to the more general EM algorithm)
- Same as likelihood is non-decreasing

$$KL(\mu_{i+1} \mid\mid D) \leq KL(\mu_i \mid\mid D)$$
